

Indole Acetamides as Inhibitors of the Hepatitis C Virus NS5B Polymerase

The present invention relates to indole and azaindole compounds, to pharmaceutical compositions containing them, to their use in the prevention and treatment of hepatitis C infections and to methods of preparation of such compounds and compositions.

Hepatitis C (HCV) is a cause of viral infections. There is as yet no adequate treatment for HCV infection but it is believed that inhibition of its RNA polymerase in mammals, particularly humans, would be of benefit. International patent applications WO 01/47883, WO 02/04425 and WO 03/000254 suggest fused ring compounds as possible inhibitors of HCV polymerase and illustrate thousands of possible benzimidazole derivatives that possess HCV polymerase inhibitory properties. However, these patent applications do not describe or reasonably suggest the preparation of any benzimidazole or azabenzimidazole substituted on all three available sites on the fused imidazole ring. WO 03/010140 and WO 03/010141 suggest further fused ring compounds as possible inhibitors of HCV polymerase and illustrate thousands of possible compounds all of which possess complex esterified side chains. The corresponding acids are suggested as intermediates only and not as HCV polymerase inhibitors. In particular none of these patent applications describe an indole or azaindole in which the indole nitrogen is substituted by an alkylamide residue.

The present invention provides compounds of the formula (I)

- 30 For use in medicine, the salts of the compounds of formula (I) will be non-toxic pharmaceutically acceptable salts. Other salts may, however, be useful in the preparation of the compounds according to the invention or of their non-toxic pharmaceutically acceptable salts. Suitable pharmaceutically acceptable salts of the

compounds of this invention include acid addition salts which may, for example, be formed by mixing a solution of the compound according to the invention with a solution of a pharmaceutically acceptable acid such as hydrochloric acid, fumaric acid, p-toluenesulfonic acid, maleic acid, succinic acid, acetic acid, citric acid, tartaric acid, carbonic acid, phosphoric acid or sulfuric acid. Salts of amine groups may also comprise quaternary ammonium salts in which the amino nitrogen atom carries a suitable organic group such as an alkyl, alkenyl, alkynyl or aralkyl moiety. Furthermore, where the compounds of the invention carry an acidic moiety, suitable pharmaceutically acceptable salts thereof may include metal salts such as alkali metal salts, e.g. sodium or potassium salts; and alkaline earth metal salts, e.g. calcium or magnesium salts.

The salts may be formed by conventional means, such as by reacting the free base form of the product with one or more equivalents of the appropriate acid in a solvent or medium in which the salt is insoluble, or in a solvent such as water which is removed *in vacuo* or by freeze drying or by exchanging the anions of an existing salt for another anion on a suitable ion exchange resin.

The present invention includes within its scope prodrugs of the compounds of formula (I) above. In general, such prodrugs will be functional derivatives of the compounds of formula (I) which are readily convertible *in vivo* into the required compound of formula (I). Conventional procedures for the selection and preparation of suitable prodrug derivatives are described, for example, in "Design of Prodrugs", ed. H. Bundgaard, Elsevier, 1985.

A prodrug may be a pharmacologically inactive derivative of a biologically active substance (the "parent drug" or "parent molecule") that requires transformation within the body in order to release the active drug, and that has improved delivery properties over the parent drug molecule. The transformation *in vivo* may be, for example, as the result of some metabolic process, such as chemical or enzymatic hydrolysis of a carboxylic, phosphoric or sulfate ester, or reduction or oxidation of a susceptible functionality.

The present invention includes within its scope solvates of the compounds of formula (I) and salts thereof, for example, hydrates.

The present invention also includes within its scope any enantiomers, diastereomers, geometric isomers and tautomers of the compounds of formula (I). It

is to be understood that all such isomers and mixtures thereof are encompassed within the scope of the invention.

The present invention further provides a compound of formula (I) or a pharmaceutically acceptable salt thereof for use in therapy.

5 In another aspect, the invention provides the use of a compound of formula (I) as defined above, or a pharmaceutically acceptable salt thereof, for the manufacture of a medicament for treatment or prevention of infection by hepatitis C virus in a human or animal.

10 A further aspect of the invention provides a pharmaceutical composition comprising a compound of formula (I) as defined above, or a pharmaceutically acceptable salt thereof, in association with a pharmaceutically acceptable carrier. The composition may be in any suitable form, depending on the intended method of administration. It may for example be in the form of a tablet, capsule or liquid for oral administration, or of a solution or suspension for administration parenterally.

15 The pharmaceutical compositions optionally also include one or more other agents for the treatment of viral infections such as an antiviral agent, or an immunomodulatory agent such as α -, β - or γ -interferon.

In a further aspect, the invention provides a method of inhibiting hepatitis C virus polymerase and/or of treating or preventing an illness due to hepatitis C virus,
20 the method involving administering to a human or animal (preferably mammalian) subject suffering from the condition a therapeutically or prophylactically effective amount of the pharmaceutical composition described above or of a compound of formula (I) as defined above, or a pharmaceutically acceptable salt thereof. "Effective amount" means an amount sufficient to cause a benefit to the subject or at least to

The dosage rate at which the compound is administered will depend on a variety of factors including the activity of the specific compound employed, the metabolic stability and length of action of that compound, the age of the patient, body weight, general health, sex, diet, mode and time of administration, rate of excretion,
30 drug combination, the severity of the particular condition and the host undergoing therapy. Suitable dosage levels may be of the order of 0.02 to 5 or 10 g per day, with oral dosages two to five times higher. For instance, administration of from 10 to 50 mg of the compound per kg of body weight from one to three times per day may be in

order. Appropriate values are selectable by routine testing. The compound may be administered alone or in combination with other treatments, either simultaneously or sequentially. For instance, it may be administered in combination with effective amounts of antiviral agents, immunomodulators, anti-infectives or vaccines known to those of ordinary skill in the art. It may be administered by any suitable route, including orally, intravenously, cutaneously and subcutaneously. It may be administered directly to a suitable site or in a manner in which it targets a particular site, such as a certain type of cell. Suitable targeting methods are already known.

The present invention also provides a process for the preparation of compounds of formula (I).

According to a general process (A), compounds of formula (I) may be prepared by reacting a compound of formula (II) with a compound of formula (III):

wherein X^1 , X^2 , X^3 , X^4 , R^1 , R^2 , A^1 and Ar^1 are as defined for formula (I). The reaction is effected in the presence of a Pd(0) catalyst under conditions typical for the Suzuki reaction.

Alternatively, according to a general process (B), compounds of formula (I) may be prepared by reacting a compound of formula (IV) with a compound of formula (V):

wherein X^1 , X^2 , X^3 , X^4 , A^1 , Ar^1 , n , R^1 and R^2 are as defined for formula (I). The reaction is conveniently performed in the presence of a coupling reagent, such as O-(7-azabenzotriazol-1-yl)- N,N,N',N' -tetramethyluronium hexafluorophosphate, or a coupling reagent on a polystyrene resin, such as PS-carbodiimide, and a base, such as diisopropylethylamine, in a solvent.

Suitable solvents include dimethylformamide and dichloromethane.

Alternatively, according to a general process (C), compounds of formula (I) where X^2 is CR^3 and R^3 is $\text{C}(\text{O})\text{NR}^9\text{R}^{10}$ may be prepared by reacting a compound of formula (VI) with a compound of formula (VII):

wherein X^1 , X^3 , X^4 , A^1 , Ar^1 , n , R^1 , R^2 , R^9 and R^{10} are as defined for formula (I). The reaction is essentially in the same manner as general process (B).

Alternatively, according to a general process (D), compounds of formula (I), where the (aza)indolyl nitrogen atom is suitably protected, may be prepared by reacting a compound of formula (VIII) with a compound of formula (IX):

where P is a suitable protecting group and wherein X^1 , X^2 , X^3 , X^4 , A^1 and Ar^1 are as defined for formula (I). The reaction is effected in the presence of a Pd(0) catalyst, a suitable ligand, such as tri-*tert*-butylphosphine or triphenylphosphine, and a salt, such as caesium fluoride, potassium phosphate or sodium hydrogencarbonate, in a suitable solvent at a temperature between 20°C and the reflux temperature of the solvent. Suitable solvents include organic solvents such as dioxane, dimethoxyethane, tetrahydrofuran or dimethylformamide. Suitable protecting groups include *tert*-butyloxycarbonyl.

Alternatively, according to a general process (E), compounds of formula (I) where X^2 is CR^3 and R^3 is $C(O)NR^9R^{10}$ and R^9 is SO_2R^{11} may be prepared by reacting a compound of formula (VI) with a compound of formula (X):

wherein X^1 , X^3 , X^4 , A^1 , Ar^1 , n , R^1 , R^2 , R^{10} and R^{11} are as defined for formula (I). The reaction is conveniently effected in the presence of an activator, such as DMAP, and/or a dehydrating agent, such as EDCI in a suitable solvent, such as dichloromethane, dimethylformamide or tetrahydrofuran.

Further details of suitable procedures will be found in the accompanying Examples. For instance, compounds of formula (I) can be converted into other compounds of formula (I) using synthetic methodology well known in the art.

Thus, for instance, the compound of formula (I) where X^2 is CR^3 and R^3 is CO_2H may be converted to the compound of formula (I) where R^3 is 1*H*-tetrazol-5-yl by conversion of the carboxylic acid to the amide, for example by treatment with ammonium hydrogen carbonate and di-*tert*-butyl dicarbonate, followed by conversion of the amide to the nitrile, for example by treatment with triethylamine followed by trifluoroacetic anhydride, and then conversion of the nitrile to the tetrazolyl group using, for example tributyltin azide in a suitable solvent, such as toluene, at a temperature between 20°C and the reflux temperature of the solvent.

In a similar manner, the compound of formula (I) wherein X^2 is CR^3 and R^3 is 5-oxo-4,5-dihydro-1,2,4-oxadiazol-3-yl may also be prepared. Thus, following the procedure described above, instead of conversion to the tetrazolyl group, the nitrile

group may be converted to the 5-oxo-4,5-dihydro-1,2,4-oxadiazolyl group using hydroxylamine followed by carbonyldiimidazole.

Compounds of formulae (II) to (X) are either known compounds or may be prepared by conventional methodology well known to one of ordinary skill in the art using, for instance, procedures described in the accompanying Examples, or by alternative procedures which will be readily apparent.

For example, compounds of formula (II) may be prepared by reacting a compound of formula (XI) with a compound of formula (V):

10

wherein X^1 , X^2 , X^3 , X^4 , A^1 and n are as defined for formula (I). The reaction is essentially effected in the same manner as general process (B).

Compounds of formula (XI) may be prepared by reacting a compound of formula (XII) with a compound of formula (XIII):

15

(XIII)

The reaction is effected by treatment of the compound of formula (XII) with a deprotonating agent, such as sodium hydride, followed by addition of the compound of formula (XIII) and then removal of the ester under suitable conditions. Suitable conditions for deesterification depend on the ester and may include acid or base hydrolysis or hydrogenation. Suitable conditions for acid hydrolysis include trifluoroacetic acid in a suitable solvent, such as dichloromethane.

25

The compound of formula (XII) where A^1 is cyclohexyl may be prepared from the compound of formula (XIV):

wherein X^1 , X^2 , X^3 and X^4 are as defined for formula (I), by alkylation at the
 5 3-position of the compound of formula (XIV) using a deprotonating agent, such as
 lithium hydride or sodium hydride, followed by 3-bromocyclohex-1-ene, in a suitable
 solvent, such as DMF. The alkylated product is then hydrogenated to remove the
 double bond of the cyclohexenyl group. Suitable hydrogenation conditions include
 the use of hydrogen in the presence of a catalyst, such as palladium on charcoal. The
 10 hydrogenated product is then brominated at the 2-position of the (aza)indole ring
 using a suitable brominating agent, such as NBS.

Compounds of formula (IV) where A^1 is cyclohexyl may be prepared from the
 compound of formula (XV):

15

wherein X^1 , X^2 , X^3 , X^4 and Ar^1 are as defined for formula (I), by alkylation at the
 3-position of the compound of formula (XV) using the general process as hereinbefore
 described for the preparation of the compound of formula (XII). This step is followed
 20 by substitution on the nitrogen atom of the (aza)indole system using the general
 process as hereinbefore described for the preparation of the compound of formula
 (XI).

Compounds of formula (XV) may be prepared by reacting a compound of
 formula (XVI) with a compound of formula (XVII):

25

wherein X^1 , X^2 , X^3 , X^4 and Ar^1 are as defined for formula (I) and Z is Br, I or OTf.

The reaction is conveniently effected in a suitable solvent, such as DMF, suitably in the presence of a base, such as tetramethylguanidine, and a catalyst, such as bis-

5 triphenylphosphine palladium(II) chloride/copper(I) iodide.

Compounds of formula (XVI) may be prepared from the compound of formula (XVIII):

10 by reaction with trifluoroacetic anhydride followed by treatment with trifluoromethanesulfonyl anhydride.

Compounds of formula (XI) where the carboxylic acid remains protected may alternatively be formed by bromination of the equivalent trimethylsilyl compound. Bromination may be performed using, for example, N-bromosuccinimide, in a suitable
 15 solvent. Suitable solvents include halogenated hydrocarbons, such as dichloromethane. The trimethylsilyl equivalent may be formed by the reaction of compound of formula (XIX) with the compound of formula (XX):

20 wherein X^1 , X^2 , X^3 , X^4 and A^1 are as defined for formula (I) and hal represents a suitable halogen atom, such as bromine or iodine.

The reaction is conveniently effected under basic conditions, for example in the presence of sodium carbonate, and in the presence of a Pd(II) salt, such as
 25 Pd(dppf)Cl₂, in a suitable solvent, such as DMF. The reaction mixture may be heated, for example in a microwave. The resultant product is then reacted with a compound of formula (XIII) using the process described for the preparation of the compound of formula (XI) to provide the desired product.

Compounds of formula (VIII) can be made by stannylation of the corresponding halo compound, especially the bromo equivalent, using a suitable stannylation agent, such as tri-butyltin chloride, with a lower alkyl lithium such as butyllithium.

When referring to these preformulation compositions as homogeneous, it is meant that the active ingredient is dispersed evenly throughout the composition so that the composition may be readily subdivided into equally effective unit dosage forms
 25 such as tablets, pills and capsules. This solid preformulation composition is then subdivided into unit dosage forms of the type described above containing from 0.1 to about 500 mg of the active ingredient of the present invention. Typical unit dosage forms contain from 1 to 100 mg, for example 1, 2, 5, 10, 25, 50 or 100 mg, of the

active ingredient. The tablets or pills of the novel composition can be coated or otherwise compounded to provide a dosage form affording the advantage of prolonged action.

The liquid forms in which the novel compositions of the present invention may be incorporated for administration orally or by injection include aqueous solutions, suitably flavoured syrups, aqueous or oil suspensions, and flavoured emulsions with edible oils such as cottonseed oil, sesame oil, coconut oil or peanut oil, as well as elixirs and similar pharmaceutical vehicles. Suitable dispersing or suspending agents for aqueous suspensions include synthetic and natural gums such as tragacanth, acacia, alginate, dextran, sodium carboxymethylcellulose, methylcellulose, polyvinylpyrrolidone or gelatin.

In the treatment of infection due to hepatitis C, a suitable dosage level is about 0.01 to 250 mg/kg per day, preferably about 0.05 to 100 mg/kg per day, and especially about 0.05 to 5 mg/kg per day. The compounds may be administered on a regimen of 1 to 4 times per day. Most suitably the administration is orally using a unit dose as previously indicated.

In a further aspect this invention provides the use of a compound of formula (I) or a pharmaceutically acceptable salt thereof in the manufacture of a medicament for the treatment of infection by hepatitis C virus. Most suitably the medicament is in unit dose form adapted for oral administration as indicated hereinbefore.

In another aspect this invention provides the use of a compound of formula (I) or a pharmaceutically acceptable salt thereof for the treatment of infection by hepatitis C virus in a mammal and preferably in a human. Most suitably the treatment is effected by oral administration of a unit dose form as indicated hereinbefore.

The following Examples illustrate the preparation of compounds according to the invention.

The compounds of the invention were tested for inhibitory activity against the HCV RNA dependent RNA polymerase (NS5B) in an enzyme inhibition assay (example i)) and a cell based sub-genomic replication assay (describe in example ii)). The compounds generally have IC₅₀'s below 5 μ M in the enzyme assay and EC₅₀'s below 20 μ M in the cell based assay. For example, 3-cyclohexyl-1-(2-{methyl[(1-methylpiperidin-2-yl)methyl]amino}-2-oxoethyl)-2-phenyl-1*H*-indole-6-carboxylic acid trifluoroacetate had an IC₅₀ of 14 nM in the enzyme assay and an EC₅₀ of 270 nM in the cell based assay.

10 **i) In-vitro HCV NS5B Enzyme Inhibition Assay**

WO 96/37619 describes the production of recombinant HCV RdRp from insect cells infected with recombinant baculovirus encoding the enzyme. The purified enzyme was shown to possess *in vitro* RNA polymerase activity using RNA as template. The reference describes a polymerisation assay using poly(A) and oligo(U) as a primer or an heteropolymeric template. Incorporation of tritiated UTP or NTPs is quantified by measuring acid-insoluble radioactivity. The present inventors have employed this assay to screen the various compounds described above as inhibitors of HCV RdRp.

Incorporation of radioactive UMP was measured as follows. The standard reaction (50 μ l) was carried out in a buffer containing 20 mM tris/HCl pH 7.5, 5 mM MgCl₂, 1 mM DTT, 50 mM NaCl, 0.03% N-octylglucoside, 1 μ Ci [³H]-UTP (40 Ci/mmol, NEN), 10 μ M UTP and 10 μ g/ml poly(A) or 5 μ M NTPs and 5 μ g/ml heteropolymeric template. Oligo(U)₁₂ (1 μ g/ml, Genset) was added as a primer in the assay working on Poly(A) template. The final NS5B enzyme concentration was 5 nM. The order of assembly was: 1) compound, 2) enzyme, 3) template/primer, 4) NTP. After 1 h incubation at 22 °C the reaction was stopped by adding 50 μ l of 20% TCA and applying samples to DE81 filters. The filters were washed thoroughly with 5% TCA containing 1M Na₂HPO₄/NaH₂PO₄, pH 7.0, rinsed with water and then ethanol, air dried, and the filter-bound radioactivity was measured in the scintillation counter. Carrying out this reaction in the presence of various concentrations of each compound set out above allowed determination of IC₅₀ values by utilising the formula:

$$\% \text{ Residual activity} = 100/(1+[I]/IC_{50})^s$$

where [I] is the inhibitor concentration and "s" is the slope of the inhibition curve.

5 ii) Cell based HCV Replication Assay

Cell clones that stably maintain subgenomic HCV replicon were obtained by transfecting Huh-7 cells with an RNA replicon identical to I₃₇₇neo/NS3-3'/wt described by Lohmann *et al.* (1999) (EMBL-genbank No. AJ242652), followed by selection with neomycin sulfate (G418). Viral replication was monitored by measuring the expression of the NS3 protein by an ELISA assay performed directly on cells grown in 96 wells microtiter plates (Cell-ELISA) using the anti-NS3 monoclonal antibody 10E5/24 (as described by *De Francesco, Raffaele; Migliaccio, Giovanni; Paonessa, Giacomo. Hepatitis C virus replicons and replicon enhanced cells. PCT Int. Appl. WO 0259321 A2 20020801*). Cells were seeded into 96 well plates at a density of 10⁴ cells per well in a final volume of 0.1 ml of DMEM/10% FCS. Two hours after plating, 50 µl of DMEM/10% FCS containing a 3x concentration of inhibitor were added, cells were incubated for 96 hours and then fixed for 10' with ice-cold isopropanol. Each condition was tested in duplicate and average absorbance values were used for calculations. The cells were washed twice with PBS, blocked with 5% non-fat dry milk in PBS + 0.1% Triton X100 + 0.02% SDS (PBSTS) and then incubated o/n at 4⁰ C with the 10E5/24 mab diluted in Milk/PBSTS. After washing 5 times with PBSTS, the cells were incubated for 3 hours at room temperature with Fc specific anti-mouse IgG conjugated to alkaline phosphatase (Sigma), diluted in Milk/PBSTS. After washing again as above, the reaction was developed with p-Nitrophenyl phosphate disodium substrate (Sigma) and the absorbance at 405/620 nm read at intervals. For calculations, we used data sets where samples incubated without inhibitors had absorbance values comprised between 1 and 1.5. The inhibitor concentration that reduced by 50% the expression of NS3 (IC₅₀) was calculated by fitting the data to the Hill equation,

$$30 \quad \text{Fraction inhibition} = 1-(A_i-b)/(A_0-b) = [I]^n / ([I]^n + IC_{50})$$

where:

- A_i = absorbance value of HBI10 cells supplemented with the indicated inhibitor concentration.

- A_0 = absorbance value of HBI10 cells incubated without inhibitor.
- b = absorbance value of Huh-7 cells plated at the same density in the same microtiter plates and incubated without inhibitor.
- n = Hill coefficient.

iii) General Procedures

All solvents were obtained from commercial sources (Fluka, puriss.) and were used without further purification. With the exception of routine deprotection and coupling steps, reactions were carried out under an atmosphere of nitrogen in oven
10 dried (110 °C) glassware. Organic extracts were dried over sodium sulfate, and were concentrated (after filtration of the drying agent) on rotary evaporators operating under reduced pressure. Flash chromatography was carried out on silica gel following published procedure (W.C. Still *et al.*, J. Org. Chem. 1978, 43, 2923) or on automated or semi-automated flash chromatography systems utilising pre-packed columns.

15 Reagents were usually obtained directly from commercial suppliers (and used as supplied) but a limited number of compounds from in-house corporate collections were utilised. In the latter case the reagents are readily accessible using routine synthetic steps that are either reported in the scientific literature or are known to those skilled in the art.

20 ^1H nmr spectra were recorded on Bruker AM series spectrometers operating at (reported) frequencies between 300 and 600 MHz. Chemical shifts (δ) for signals corresponding to non-exchangeable protons (and exchangeable protons where visible) are recorded in parts per million (ppm) relative to tetramethylsilane and are measured using the residual solvent peak as reference. Signals are tabulated in the order:
25 multiplicity (s, singlet; d, doublet; t, triplet; q, quartet; m, multiplet; br, broad, and combinations thereof); coupling constant(s) in hertz; number of protons. Mass spectral (MS) data were obtained on a Perkin Elmer API 100 operating in negative (ES⁻) or positive (ES⁺) ionization mode and results are reported as the ratio of mass over charge (m/z) for the parent ion only. Preparative scale HPLC separations were
30 carried out on a Waters Delta Prep 4000 separation module, equipped with a Waters 486 absorption detector or on a Thermoquest P4000 equipped with a UV1000 absorption detector. In all cases compounds were eluted with linear gradients of water

and acetonitrile both containing 0.1% TFA using flow rates between 15 and 25 mL/min.
